

## **Location recommendation for opening a restaurant**

IBM Data Science Capstone Project

Apoorva Sharma

### **Introduction**

Opening a restaurant can be a very profitable business but lack of demand can cause many restaurant to close within the first year of opening. Success of a restaurant depends on many factors, to name a few - location, competition and quality of the food. This project tries to find an optimal recommendation for opening an Indian restaurant in Toronto by taking all the above mentioned factors in consideration. Foursquare API has been used to determine the optimal location to open an Indian Restaurant. For Indian Restaurant specifically, location and competition are both considered while providing a recommendation. If there are too many Indian Restaurants in the local vicinity, the profitability of the restaurant may severely decrease. Additionally, opening a restaurant in a higher income location would increase the profitability of the business compared to opening the restaurant in a poor income locality.

To demonstrate the process of picking a location for a client opening a business, the project will focus on answering the following question: "If the client wanted to open an Indian Restaurant in Toronto, what areas are the best options to open the restaurant?" For an Indian Restaurant, the location and competition are both determined by where the restaurant is opened. If there are too many Indian Restaurants in the local vicinity, the profitability of the restaurant will be severely decreased. Additionally, starting a restaurant in a location with higher income would increase the profitability of the business over starting in a poorer area.

### **Data**

Foursquare API is used to determine the average house price in different neighborhoods which helps in estimating the average income of the inhabitants. Foursquare API is also used in determining population distribution of each area, the number of Indian Restaurant in each neighborhood and the number of total restaurants in each neighborhood. The data is then used to cluster different postal codes to determine the optimal location to open the restaurant.

To answer the business problem, the following factors have to be extracted from various data sources:

- Population & Ethnic Distribution of Each Neighborhood (Toronto Census)
- Income Distribution of Each Neighborhood (Toronto Census)
- Number of Restaurants in Each Neighborhood (Foursquare API)
- Number of Indian Restaurants in Each Neighborhood (Foursquare API)

### **Methodology**

The first step of the project was to combine the Toronto dataset, containing the postal code, borough, neighborhood name, latitude and longitude for each postal code in Toronto, and the census dataset. The first four columns of combined dataframe can be seen in Figure 7 of the Appendix.

Using the income distribution for each neighborhood, the spending power of each area

was calculated using the median of each category weighted by the number of people in that income category. Thus, the spending power represents the overall capital of each area (i.e. total income of the inhabitants). Since the spending power for each area is considerably large and the relative strength is difficult to visualize, the spending power for each area was standardized. The next step was to visualize the location of the various postal codes within Toronto to obtain a general understanding the location (Figure 1). As seen from the map, the postal codes are densely clustered near downtown Toronto and spread out as the distance from downtown increases. This is important because while some postal codes might not have many restaurants, if the area is located near downtown, adjacent regions can heavily impact the profitability of the restaurant.

Figure 1: Location of each postal code within Toronto, Canada.

Now that the region has been clearly visualized, the Foursquare API was used to explore each neighborhood and return the top 200 venues within 2,000 meters (1.2 miles) of the longitude and latitude for each postal code. The extracted venue categories were encoded using one-hot encoding and the total restaurants and Indian restaurants in each region were calculated (Figure 2).

	Neighborhood	Total Restaurants	Indian Restaurants
0	Adelaide, King, Richmond	33	0
1	Agincourt	52	3
2	Agincourt North, L'Amoreaux East, Milliken, St...	55	3
3	Albion Gardens, Beaumond Heights, Humbergate, ...	21	4
4	Alderwood, Long Branch	40	0
5	Bathurst Manor, Downsview North, Wilson Heights	22	0
6	Bayview Village	14	0
7	Bedford Park, Lawrence Manor East	44	1
8	Birch Cliff, Cliffside West	14	0
9	Bloordale Gardens, Eringate, Markland Wood, Ol...	5	0

With the resulting data, the Postal Code, Borough name, Latitude, Longitude and Density columns of each region were dropped from the DataFrame. Then, the population, area, spending power, total number of restaurants and the number of Indian restaurants were used to train a k-Means clustering algorithm with 5 clusters (Figure 3). The characteristics of the resulting clusters can be found in Table 1.

## Results

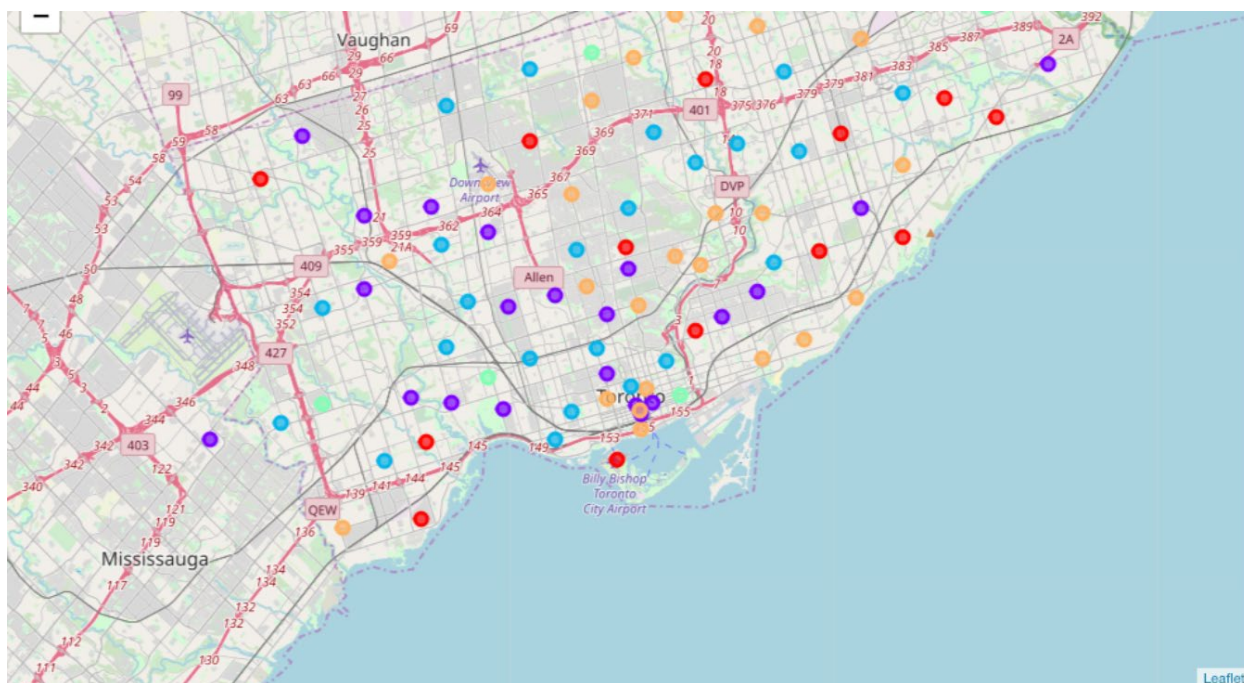

Figure 3: Result of the clustering algorithm. Cluster 0 = Red Cluster 1 = Purple Cluster 2 = Blue Cluster 3 = Turquoise Cluster 4 = Orange

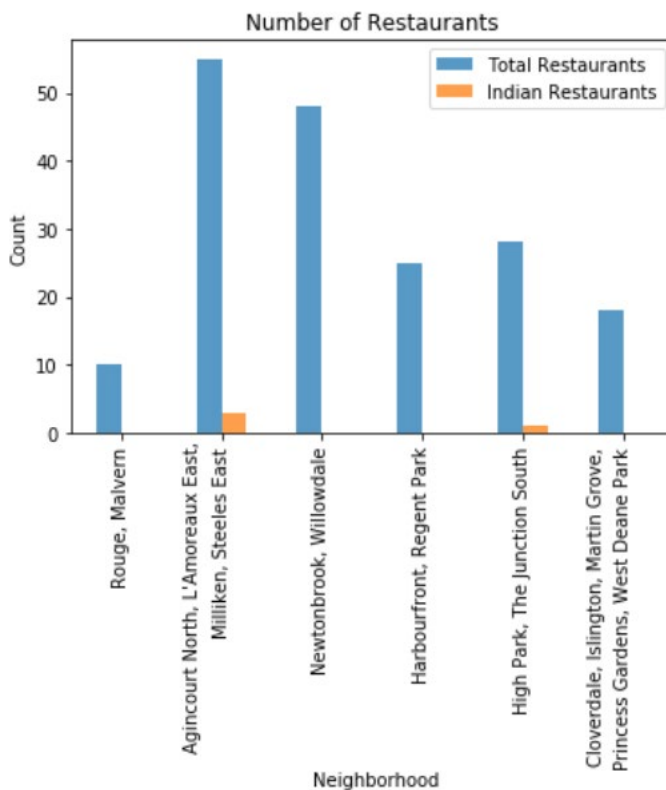

Cluster	Characteristics
---------	-----------------

<b>Cluster 0</b>	Positive Spending Power (0.3 – 1.8)
<b>Cluster 1</b>	Negative Spending Power (-1.2 -- -0.8)
<b>Cluster 2</b>	Near Zero Spending Power (-0.5 – 0.5)
<b>Cluster 3</b>	High Positive Spending Power (1.7+)
<b>Cluster 4</b>	Negative Spending Power (-0.8 – 0) With Large Number of Restaurant

Table 1: Characteristics of the clusters resulting from k-Means clustering algorithm

	Borough	Neighborhood	Latitude	Longitude	Cluster Labels	Population	Area	Spending Power	Total Restaurants	Indian Restaurants
0	Scarborough	Rouge, Malvern	43.806686	-79.194353	3	90290	45.74	1.756524	10	0
14	Scarborough	Agincourt North, L'Amoreaux East, Milliken, St...	43.815252	-79.284577	3	86468	19.96	1.712083	55	3
21	North York	Newtonbrook, Willowdale	43.789053	-79.408493	3	90362	13.80	2.350813	48	0
46	Downtown Toronto	Harbourfront, Regent Park	43.654260	-79.360636	3	76716	8.01	3.838132	25	0
70	West Toronto	High Park, The Junction South	43.661608	-79.464763	3	82712	10.51	2.841538	28	1
79	Etobicoke	Cloverdale, Islington, Martin Grove, Princess ...	43.650943	-79.554724	3	105450	26.38	3.748670	18	0

Figure 4: Data from neighborhoods belonging to Cluster 3

Figure 5: These plots shows the characteristics of neighborhoods belonging to cluster 3.

## Discussion

From the results of the clustering algorithm, it was determined that neighborhoods corresponding to cluster 3 were the best choice for opening an Indian restaurant based on the normalized spending power and population. This narrowed down possible locations to six different areas. Using the results in Figure 5, the Agincourt North, L'Amoreaux East, Milliken, Steeles East region the Newtonbrook, Willowdale region and the Harbourfront, Regent Park region were eliminated due to the large number of restaurants in the area.

From the three remaining regions, I would recommend that the client open his/her restaurant in either the Rouge, Malvern region or the Cloverdale, Islington, Martin Grove, Princess Gardens, West Deane Park region. Both regions have very few restaurants and are farther away from the downtown area. While the Cloverdale, Islington, Martin Grove, Princess Gardens, West Deane Park region has a higher spending power and population, the Rouge, Malvern region has a higher percentage of South Asians and thus the optimal region to open the Indian Restaurant.

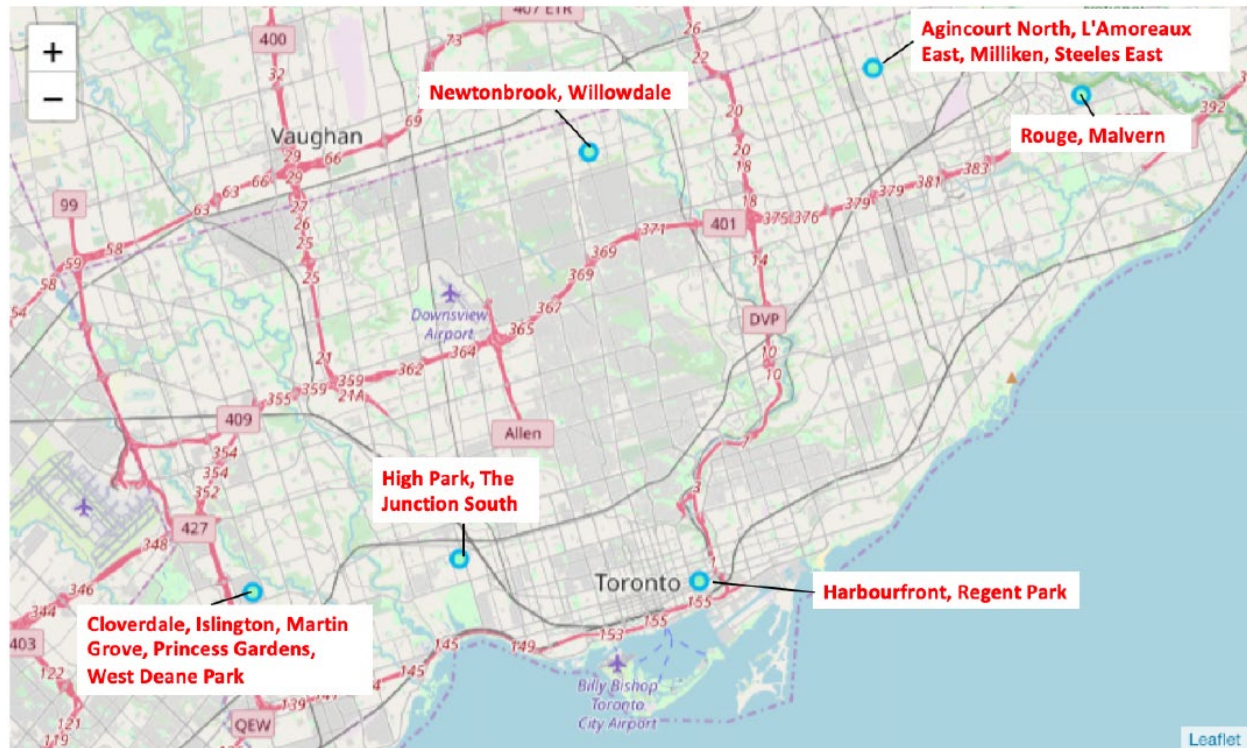

Figure 6: Map of Toronto with the neighborhoods in Cluster 3 labeled.

## Conclusion

Opening a restaurant is a complex task that can lead to a large monetary loss if not done properly. Thus, extensive research about the area would greatly increase the likelihood of the restaurant succeeding. From the project above, I demonstrated the workflow necessary for a client to determine what area the restaurant should open. For specifically, I determined that the optimal location to open an Indian restaurant in Toronto should be in the Rouge, Malvern region.

Figure 7: The above image shows the first 5 rows of the imported DataFrame used during the project. The DataFrame contains the postal code, borough name, neighborhood name, latitude and longitude of each postal code in Toronto, Canada. Additionally, the table contains the population in each neighborhood, population density (people per square kilometer), area (squared kilometers) and the income distribution in Canadian dollars. Finally, the ethnicity distribution in % for each neighborhood is also included.
